

Actinic granuloma

Actinic granuloma is a granulomatous reaction occurring in profoundly sun-damaged skin.

Appearing as an erythematous papule, the lesion expands as a red, raised ring, often with central atrophy being evident.

Lesions are usually asymptomatic

Treatment:

- The application of potent topical glucocorticoids to the advancing edge is often effective.
- Intralesional triamcinolone can also be effective.
- Cryotherapy can also be used.
