

**Pitted Keratolysis** is a bacterial infection of the skin on the feet. It is caused by a group of bacteria called *Corynebacterium* and *Bacillus*. The disease is characterized by small, yellowish, crater-like lesions on the skin. These lesions are surrounded by a slightly raised, inflamed border. The disease is most common in people who wear shoes for long periods of time, especially those who wear shoes that are not well-ventilated. The disease is also more common in people who have a history of foot problems, such as athlete's foot or fungal infections. The disease is usually treated with antibiotics, and the lesions usually disappear within a few weeks of treatment.
