

BECKER'S NEVUS (619) is a benign skin condition characterized by a large, irregular, light brown pigmented area on the skin. It is caused by an overgrowth of melanocytes, which are the cells responsible for producing melanin, the pigment that gives skin its color. Becker's nevus is most commonly found on the arms, legs, and torso, and it typically appears during childhood or adolescence. The condition is harmless and does not require treatment, although some people may choose to have it removed for cosmetic reasons. It is important to note that Becker's nevus is not the same as a mole, which is a different type of skin lesion.
