

**Erythema Induratum** erythema induratum of Bazin and lobular vasculitis are used as synonyms for the same disease. Erythema induratum is a chronic, recurrent, ulcerating disease of the lower extremities, especially the posterior aspects of the lower leg. It is characterized by the presence of nodules, plaques, ulcers, and epithelioid abscesses. The disease is thought to be a form of pyoderma gangrenosum. The lesions are typically painless and are often associated with systemic lupus erythematosus. The disease is more common in women than in men. The lesions are typically located on the posterior aspects of the lower leg, but they can also occur on the arms, face, and trunk. The lesions are typically painless and are often associated with systemic lupus erythematosus. The disease is more common in women than in men. The lesions are typically located on the posterior aspects of the lower leg, but they can also occur on the arms, face, and trunk.
