

This condition is often characterized by the presence of folliculitis, which is a localized infection of the hair follicle. The lesions are typically small, red, and raised, and they may be accompanied by itching or pain. The condition is most commonly caused by the bacterium Staphylococcus aureus, which is a common skin flora. The lesions are often found on the face, neck, and upper torso. The condition is usually self-limiting and resolves within a few days. Treatment is typically not necessary, but over-the-counter antibiotics or topical antiseptics may be used to reduce the risk of infection. In severe cases, oral antibiotics may be prescribed. The condition is often associated with poor hygiene, such as not washing the skin properly or using contaminated towels. It is also more likely to occur in people who have a weakened immune system or who are taking antibiotics. The condition is not contagious and does not lead to long-term complications. It is important to keep the skin clean and dry to prevent the condition from recurring. If the condition persists or worsens, it is important to see a healthcare professional for further evaluation and treatment.
