

Impetigo is a common skin infection caused by Staphylococcus aureus or Streptococcus pyogenes. It is characterized by the formation of small, crusted lesions, often referred to as "honeycrusts". Impetigo can be bullous or non-bullous. Bullous impetigo is characterized by the formation of large, fluid-filled blisters. Non-bullous impetigo is characterized by the formation of small, crusted lesions. Impetigo is most commonly found on the face and neck, but it can also occur on other parts of the body. It is highly contagious and can spread easily from person to person. Impetigo is usually treated with antibiotics, either orally or topically. In severe cases, hospitalization may be required.
