

Psoriasis

Psoriasis may be divided into psoriasis vulgaris, generalized pustular psoriasis, and localized pustular psoriasis.

Psoriasis Vulgaris **Clinical Features**

Psoriasis vulgaris is a common chronic inflammatory skin disorder that affects approximately 1.5% to 2%

associated with acute group A ~-hemolytic streptococcal infections . Involvement of the nails is common

Psoriatic arthritis characteristically involves the terminal interphalangeal joints, but frequently the large joints

Generalized Pustular Psoriasis

Clinical Features

Generalized pustular psoriasis includes (a) acute generalized pustular psoriasis (von Zumbusch type and

This cutaneous eruption is characterized by the presence of variable numbers of sterile pustules appearing

The four variants of generalized pustular psoriasis show considerable resemblance and overlapping in the

mainly in the mode of onset and the distribution of the lesions. Frequently, all four diseases show oral pu

is the term used when the pust

Pustulosis palmaris et plantaris is a chronic, relapsing disorder occurring on the palms, soles, deep

Psoriasis and Acquired Clinical Features

The association between psoriasis and human immunodeficiency virus (HIV) infection is controversial. A study of 1000 patients with psoriasis found that 10% were HIV positive. The association between psoriasis and HIV infection was not statistically significant. The study was limited by its cross-sectional design and the use of self-reported HIV status. The association between psoriasis and HIV infection needs to be further investigated.

Psoriasis Vulgaris

Histopathology

The histologic picture of psoriasis vulgaris varies considerably with the stage of the lesion and usually is

The earliest pinhead-sized macules or smooth-surfaced papules show subtle histologic changes with a p

exocytosis of neutrophils, they may aggregate in the uppermost portion of the spinous layer to form small

In the fully developed lesions of psoriasis, as best seen at the margin of enlarging plaques, the histologic

Of the listed features, only the spongiform pustules of Kogoj and Munro microabscesses are truly diagnostic of psoriasis.

The rete ridges show considerable elongation and extend downward to a uniform level, resulting in regularity of the epidermal surface.

show thickening ("clubbing") in their lower portion. Not infrequently, adjacent rete ridges seem to coalesce

The suprapapillary epidermis appears relatively thin in comparison with the markedly elongated rete ridg

In some instances the cornified layer consists entirely of confluent parakeratosis forming a platelike scale.

Munro microabscesses are located within the parakeratotic areas of the cornified layer . They consist of

The dermal papillae, in accordance with the elongation and basal thickening of the rete ridges, are elong

An entirely typical histologic picture as described earlier is not always found, even if the biopsy specimen

indicates a fluctuation in the activity of the psoriasis.

The bleeding points that may be produced by gentle scraping of the skin (Au spitz sign) correspond to th
