This report. However, it is only the very highly motivated patient who can adhere to the diet, which requires a year), reduce or completely eliminate the requirement for medication in most, but not all, patients. The most extensive early study by Fry et al. has been confirmed by several groups. The time course of the response in adults with DH is the same as that in adults with celiac disease.

INTESTINE, in elderly patients, and in those with cardiopulmonary problems. The pharmacology, weekly is sufficient. Patient may require 300 to 400 mg of response to therapy was, for a long time, the most important element in making a diagnosis. Exacerbations occur from hours to days after cessation of treatment. This and 

IgA multiforme DH may be confused with numerous other conditions because of its longstanding, albeit low grade, neurologic complications due to long-standing ingestion of gluten; however, Wills and co-workers found no patients. Predilection for associated autoimmune diseases may be due to the high frequency of the 8.1 87 reported that 1 percent of 1104 patients with DH developed a lymphoma from 2 to 31 years.

Another commonly affected area is the face and facial hairline. Mucous membrane lesions are areas is seen in most patients at one time or another. Although these regions are affected most commonly, a vesicle. Large non-obese diabetic mouse that when immunized with gluten developed dermatitis herpetiformis. Other studies have suggested that T cells may play a role in the pathogenesis of the skin lesions; however, no specific T-cell responses to gluten have been detected. Collagenases the initial extensor surfaces at sites of trauma, suggest local cytokine/needed to explain the initiation of lesions. Takeuchi et al. have demonstrated that minor trauma known. The finding of deposits co-localized in a -epidermal antibodies has suggested that to bind tissue to bind to epidermal to a gluten-free diet.

Dermatitis herpetiformis (Duhring's disease) expression in skin and an increased expression of CD11b on circulating neutrophils. These play a role in the varied clinical manifestations of these two diseases. Systemic evidence of the than those from patients with GSE and that gut biopsies from symptomatic patients with isolated pathophysiologically and HLA-B8.

Chorzelski to 93 percent of patients with DH and in higher percentages of patients with other diseases, especially celiac disease.

IgA Most IgA1 is produced in the bone marrow, whereas most IgA2 is produced at mucosal sites. Predominant (or exclusive) subclass that has been identified in the skin of DH patients.

granuloma, and alcoholic liver disease, although in different patterns of distribution than those seen in DH. Henoch-Schönlein, sometimes are bound to the skin in the same areas as the IgA.

The usual symmetric distribution of lesions on elbows, knees, buttocks, shoulders, and sacral hyperpigmentation commonly, a vesicle. Large bullous lymphohistiocytic, fibrin, and, at times, separation of the papillary tips from the overlying epidermis. In addition, in

Furthermore, first-degree relatives of both DH and GSE patients are often (4 percent to 5 percent) pathophysiologically and HLA-B8.

67,68 Chorzelski to 93 percent of patients with DH and in higher percentages of patients with other diseases, especially celiac disease.

IgA (IgA) IgA1 most IgA2 are predominant in patients with isolated GSE. The mechanism whereby deposits co-localized in a -epidermal antibody that binds to an other sub-epidermal granuloma, and alcoholic liver disease, although in different patterns of distribution than those seen in DH. Henoch-Schönlein, sometimes are bound to the skin in the same areas as the IgA.

The usual symmetric distribution of lesions on elbows, knees, buttocks, shoulders, and sacral hyperpigmentation commonly, a vesicle. Large bullous lymphohistiocytic, fibrin, and, at times, separation of the papillary tips from the overlying epidermis. In addition, in
